Abstract

The formation of successful corporate strategy among vertically integrated organizations is predicated upon a plethora of dynamic relationships among buyer-seller firms. Albeit growing in interest, there is a paucity of research that focuses on predicting the nature of interfirm relationships among Japanese keiretsu members. Discerning this knowledge can help formulate successful strategic decisions, such as whether to continue procuring parts or increasing future investments in partner firms. As studies on predicting interfirm relationships among keiretsu member firms has been scant, this research offers insights by illustrating a newer approach for making decisions regarding corporate strategy. Using data collected on transaction from Yokokai—parts suppliers of Mazda—in this study a new model is developed to predict the nature of interfirm relationships using the degree index and DEA model. The primary contribution of this research is that interfirm relationships not only depend on future trends, but are also determined by the interactions among member firms of a keiretsu.

Keywords: out-degree, rate of change, Interfirm relationship, cross-sectional interaction, Yokokai.

1. Introduction

In vertically integrated arrangements, formulation of successful corporate strategy is predicated upon a plethora of dynamic interrelationships among member organizations, such as frequently engaging in interfirm transactions, cross-firm investments, and jointly coalesce towards attaining collective, supra-organizational goals. Although there is growing interest, research on these vertically integrated organizational forms has been fragmentary. Indeed, research that focuses on predicting the nature of interfirm relationships among Japanese keiretsu members is scant. Discerning this knowledge can direct determine strategic decisions, such as whether to continue procuring parts or increasing future investments in partner firms. Accordingly, this study makes a contribution to the extant literature by illustrating a novel integrative forecasting approach for
Predicting the State of Interfirm Relationships

Predicting the state of interfirm relationships, which is not only dependent on future economic conditions, but also determined by the interactive relationships among keiretsu member organizations. This manuscript is structured as follows. Section 2 reviews the relevant literature on forecasting methods and interfirm relationships. In Section 3, the model building procedure and process for predicting interfirm relationships using our new proposed method is explicated. In Section 4, the application of the integrative forecasting approach is exemplified. In Section 5, the results of this empirical study using the data drawn from Yokokai, Mazda’s Keiretsu, is compared and contrasted to validate our new proposed integrative forecasting method vis-à-vis traditional prediction methods and approaches. Section 6 identifies limitations and offers directions for future research.

2. Background

As well-known organizational structures, Japanese keiretsu typically comprise a family of interfirm cooperative arrangements among member automotive manufacturers and their component parts suppliers. It is widely recognized that the success of corporate management of these inter-family structured business constellations and alliances depends to a large extent on interfirm relationships among partner firms. A plethora of studies on interfirm relationships have been published. For instance, Bensaou illustrated a framework for managing a portfolio of relationships among partner firms. More specifically, he (a) proposed the type of relation design a firm should choose under different external contingencies, and (b) what is the appropriate way to manage different types of relationships [1]. In another investigation, Mathijs De Vaan clarified how the composition and stability of network ties affect firm performance in industries characterized by rapid technological change [2]. All of these research studies focused on the interfirm relationships using past data sets. While offering explanations to past occurrences is important, forecasting the future developmental trends of interfirm relationships would be even more salient. Indeed, businesses place tremendous importance on the prediction in different fields, such as weather forecasting, and stock price movements [3]. In the context of keiretsu, as studies on prediction of interrelationships among interfirm partners have been sparse, this research offers insights by showing a newer approach for making decisions regarding corporate strategy. Using data collected on transaction from Yokokai—parts suppliers of Mazda—in this study a new model is developed to forecast interfirm relationship using graph theory.

3. Model Building

Generally, all forecasting methods, which include moving average and ARMA models, have focus on future trends and rate of change for time series data depending on past values of the variable being forecasted and on past prediction errors. Moreover, the input data sets are basically independent with each other. However, in case of network organizations, all indexes are connected with each other; thus, the criterion variable will vary if one of the indexes, such as degree and influence change [4-5]. Consequently, the prediction of interfirm relationships basically comprises two aspects. The first is future trends, which may exhibit increasing or decreasing values. And, the second is the rate of change for time series data. Thus, future trend will be determined by not only time series change, but also cross-sectional interaction of interfirm relationship. In this paper, time series change can be measured by least square method, and future trend will be identified by using comparative study between different term’s efficiency. That is indicative of a strong incentive to develop next transaction if the t+1 term’ efficiency is larger than its previous term. Therefore, to calculate relative efficiency another forecasting method—the DEA procedure—is proposed. Cross-sectional interaction can be calculated using graph theory, such degree, and influence of interfirm relationships. Accordingly, the procedure can be shown as below.

1. Collect adjacent matrix data from Keiretsu.
2. Calculate network indexes such as degree using graph theory. In asymmetric network, degree will be divided into out-degree and in-degree. They will used as input data sets in DEA model. Degree will be calculated as below.

\[ \text{Deg} = \sum_{i=1}^{n} a(p_i, p_k) \]  

(1)

3. Put the network indexes as input data set into DEA model with output data set. The generalized model of the CCR model is formulated as follows: Objective function

\[ \max \ \theta = \frac{\sum_{i=1}^{n} u_i x_{ij}}{\sum_{i=1}^{n} v_i x_{ij}} \]  

(2)

Subject to

[Further details of the optimization problem follow, including constraints and mathematical formulation.]

Based on degree equation, in-degree and out-degree will be calculated in Table 1 as below.

<table>
<thead>
<tr>
<th>Out-degree</th>
<th>In-degree</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>20</td>
</tr>
<tr>
<td>B</td>
<td>135</td>
</tr>
<tr>
<td>C</td>
<td>115</td>
</tr>
<tr>
<td>D</td>
<td>80</td>
</tr>
<tr>
<td>E</td>
<td>55</td>
</tr>
</tbody>
</table>

The relative efficiency of the five firms are 0.714, 1, 0.322, 0.543, 1 respectively when the sales revenue of the five firms are 100, 90, 250, 300, and 400 respectively. Suppose the regression model of out-degree of node D is $y=20x-100$ based on data sets of 9 historical term. Thus, the out-degree of B in next term will be 100. The rate of change is 0.25. Consequently, the relationships with C, and E will be 31.25, and 68.75, respectively. The new value of interfirm relation of D-C and D-E are 0.505, and 0.482, respectively. They are less than $\theta_0=0.543$; therefore, the direction of the future trend will be negative. The prediction value of D-C and D-E will be 18.75, and 41.25. It means that the relationship between D and C, and D and E will be weaker than before.

5. Empirical Studies

In order to predict the relationship of the keiretsu, data for the duration 2004 to 2008 was obtained from Yokokai, a network organization of the automotive parts suppliers. The network of Yokokai in 2004 is illustrated as in Fig. 2.
To predict interfirm relationships in 2008, the out-degree of Hiroshima Aluminum are calculated in Table 2.

Table 2. Out-degree of Hiroshima Aluminum.

<table>
<thead>
<tr>
<th>Year</th>
<th>Out-degree</th>
</tr>
</thead>
<tbody>
<tr>
<td>2004</td>
<td>76.5</td>
</tr>
<tr>
<td>2005</td>
<td>76</td>
</tr>
<tr>
<td>2006</td>
<td>79</td>
</tr>
<tr>
<td>2007</td>
<td>78.8</td>
</tr>
</tbody>
</table>

The relative efficiency of Hiroshima Aluminum is 0.04. The prediction value of out-degree in 2008 will be calculated as 80.05 using regression model. The observed value in 2008 is 81.2. The rate of change will be calculated as 1.58%. There are four companies have transactions with Hiroshima Aluminum in 2007. They are Mazda, Honda, Jatco, and Aishin AW. This rate is used to calculate the relationship and efficiency. The new efficiencies of Mazda, Honda, Jatco, and Aishin AW are 0.039, 0.092, 0.088, and 0.101, respectively. Thus, only the efficiency with Mazda is less than the former. It indicates that the future trend of the relationship with Mazda will be negative. The results of prediction and efficiency can be shown in Table 3 below.

Table 3. Prediction Results and Observed Data.

<table>
<thead>
<tr>
<th></th>
<th>Prediction</th>
<th>Observed Data Set</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mazda</td>
<td>53.04</td>
<td>48</td>
</tr>
<tr>
<td>Honda</td>
<td>8.84</td>
<td>6.9</td>

<tr>
<td>Jatco</td>
<td>10.46</td>
<td>11.5</td>
</tr>
<tr>
<td>Aishin AW</td>
<td>5.99</td>
<td>14.8</td>
</tr>
</tbody>
</table>

Basically, the traditional approach of prediction is only to calculate the trend based on time series change. To compare the traditional approach with our newer proposed method, the prediction of interfirm relationships is conducted. The value of interfirm of Hiroshima Aluminum with Mazda, Honda, and Jatco are 54.7, 7.2, and 11.25 respectively using the regression model without considering the interaction among firms to predict. The relationship with Aishin AW cannot be calculated because of lack of data. Using the observed data, prediction using our proposed method, versus prediction without considering the interaction is illustrated in Fig. 3.

Fig. 3. Prediction Results of the Relationships between Hiroshima Aluminum and its Suppliers.

Prediction 1 indicates the proposed method, which is compared with the results of Prediction 2 (or the traditional approach) in Fig. 3. All other firms exhibit similar results. Similarly, we selected KYB and compared the results using the same method, which is reported in Fig. 4.

Fig. 4. Prediction Results of the Relationships between the KYB and its Suppliers.

This study corroborates that the result of our newer proposed method is much more accurate than the traditional approach. Accordingly, the results obtained in this empirical investigation find validation and support of our integrative forecasting method.

6. Conclusion

In this paper, a new method using two integrative forecasting techniques was proposed. Using transaction data drawn from Mazda’s Yokokai, the value of interfirm relationship of Hiroshima Aluminum and KYB were selected and predicted. The results validate and corroborate that the newer method has met with empirical support.
A limitation of this paper, however, is that only one network index—degree—is used. Additional network indices, such as influence and closeness, should also be investigated to test the validity of the newer forecasting model. Furthermore, in future research studies not only transactional data, but also cross-shareholdings among member firms, should be employed.

Authors Introduction

Dr. Takao Ito

Dr. Takao Ito is Professor of Management of Technology (MOT) in Graduate School of Engineering at Hiroshima University. He is serving concurrently as Professor of Harbin Institute of Technology (Weihai) China. He has published numerous papers in refereed journals and proceedings, particularly in the area of management science, and computer science. Dr. Ito earned his Doctor degree of Economics from Kyoto University and Ph. D. of Engineering from Miyazaki University, Japan. Dr. Ito was a visiting research professor of School of Management, New Jersey Institute of Technology (NJIT) from March 29 2008 to March 28, 2009.

Dr. Tsutomu Ito

Dr. Tsutomu Ito is Assistant Professor of the Department of Business Administration at National Institute of Technology, Ube College, Japan. He has published many papers in refereed journals and proceedings, particularly in the area of industrial management, and computer science. His current research interests include internet of things (IoT), mechanical engineering, artificial intelligence (AI), automata theory, quantitative analysis of Japanese Keiretsu. He was one of the winners of the Best Paper Award in the International Conference on Artificial Life and Robotics (ICAROB) in 2015 and 2016. Dr. Ito earned his Doctor degree of Engineering from Hiroshima University, Japan in 2018.

Dr. Rajiv Mehta

Dr. Rajiv Mehta (Ph.D., Drexel University) is Professor of Marketing at Martin Tuchman School of Management, New Jersey Institute of Technology, USA. Previously, he worked for an international manufacturer of steel cables. He has co-authored four university textbooks, including Sales Force Management, 2nd ed. (2020). Focusing on sales management, global marketing channels, Keiretsus, and international strategic alliances, his research is published in Sloan Management Review, Journal of Business Research, Industrial Marketing Management, European Journal of Marketing, International Marketing Review, and Artificial Life and Robotics, among others.
Dr. Seigo Matsuno

Dr. Seigo Matsuno is Professor of the Department of Business Administration at National Institute of Technology, Ube College, Japan. He received his Ph.D. degree in Economics from Kyushu University, Japan in 2004. His current research interests are in the areas of IT management and strategy, information systems outsourcing, and interfirm relationship management. Dr. Matsuno has published several research papers and books in that area. He is a member of the Board of the Directors of Japan Society for Information and Management.

Dr. Makoto Sakamoto

Makoto Sakamoto received the Ph.D. degree in computer science and systems engineering from Yamaguchi University in 1999. He is presently an associate professor in the Faculty of Engineering, University of Miyazaki. His first interests lay in hydrodynamics and time series analysis, especially the directional wave spectrum. He is a theoretical computer scientist, and his current main research interests are automata theory, languages and computation. He is also interested in digital geometry, digital image processing, computer vision, computer graphics, virtual reality, augmented reality, entertainment computing, complex systems and so forth. He has published many research papers in that area. His articles have appeared in journals such as Information Sciences, Pattern Recognition and Artificial Intelligence, WSEAS, AROB, ICAROB, SJI, IEEE and IEICE (Japan), and proceedings of conferences such as Parallel Image Processing and Analysis, SCI, WSEAS, AROB and ICAROB.
